

Photo-Current Enhancement in the Cu/rGO/n-Cu₂O Photo-Electrode at Electrolyte Interface

S.P.A.U.K. Samarakoon¹, K.A.S.K. Hemachandra¹, C.A.N. Fernando^{1*}

Abstract

A simple method was found to fabricate Cu/rGO/n-Cu₂O photo-electrode to enhance the photocurrent with compared to the device Cu/n-Cu₂O photo-electrode at semiconductor-electrolyte interface. Reduced graphene oxide (rGO) was fabricated on a well cleaned copper sheet using electrophoretic deposition (EPD) technique to fabricate Cu/rGO. Thereafter Cu/rGO electrode was boiled in a 10⁻⁴M CuSO₄ solution to fabricate Cu/rGO/n-Cu₂O photo-electrode for the first time. Here The rGO acts as a good electron acceptor ton-Cu₂O photo-generated electrons enhancing the charge separation process suppressing the recombination process of the photo-generated charge carriers.

Keywords: n-Cu₂O, rGO, Photoelectron Chemical Cell

1. Introduction

The renewable energy sources are one of the greatest challenges facing us to address the increasing energy demand of our society. Solar energy is the largest energy source available us and can be converted into electricity through the photovoltaic effect[1]. Therefore it is encouraged the fabrication of low cost materials for energy conversion devices[2].

The potential for Cu₂O to be used in semiconducting devices has been investigated as it is timely and attractive, since this material with a band gap around 2 eV. Many researches are based on p type Cu₂O, but the simplicity of preparation and the non-toxicity of n type Cu₂O, it has considerable attention for research on this material in the past[2]. For this study n-Cu₂O layer is formed by boiling a well cleaned Cu plate in a CuSO₄ solution.

Since the beginning of the last century, carbon based systems played major role in energy conversion applications [3]. Graphene with two-dimensional structure

has been used as excellent charge transfer medium, due to its high conductivity, excellent conductivity, high mobility of charge carriers and light transmission[4-5]. Ease of synthesizing of graphene layer, graphene oxide (GO) is used. For further increasing of conductivity, reduced graphene oxide (rGO) is used. Electrophoretic deposition technique (EPD) is used to deposit rGO because of its high deposition rate, good thickness controllability, good uniformity, and simplicity of scale up coating [6].

From this study n-Cu₂O were fabricated on rGO deposited copper sheets for the first time. A photocurrent enhancement with improved absorption properties and higher steady state photocurrents were found at Cu/rGO/n-Cu₂O electrolyte interface in a photo-electrochemical cell as a low cost solar energy conversion device.

2. Experimental

Cu plates (3 cm × 1 cm) were cleaned and polished with sand papers to obtain a mirror like surface. Then the plates were thoroughly washed with distilled water.

2.1. Preparation of Graphene Oxide

The Graphene Oxide (GO) used in this study was prepared from purified natural graphite by the modified Hummers method [7]. 2 g of graphite powder was mixed with 46 ml conc. H₂SO₄ and 1 g NaNO₃ solution at 0 °C. 6 g of KMnO₄ was added slowly to the flask while the temperature kept below 15 °C with vigorous stirring for 30 minutes. The suspension was mixed until the temperature exceed 35 °C then it became a brownish in color. 92 ml of de-ionized water was added slowly while stirring for further 15 min. Finally, 10 ml of H₂O₂ (30 wt. %) solution was added slowly to the mixture and the color of the mixture change into yellow in color. The mixture was centrifuged and

washed with water and HCl based on a volume ratio 10:1 for several times to remove the residual ions. The powder was dried at room temperature in a vacuum desiccator for an overnight.

2.2. Deposition of rGO Layer

At first GO was dispersed in distilled water pH of 4. Fig.1.a shows the diagram of the EPD cell experiment. When 10V DC voltage was applied between Pt plate and Cu plate, the rGO platelets migrated towards the Cu plate (positive electrode). After deposition, samples were dried[6].

Fig. 1.a: Experimental Setup of the EPD Technique

2.3. Preparation of Cu/rGO/n-Cu₂O layer

Cu/rGO substrate was immersed in a 5×10^{-3} M CuSO₄ solution and boiled to obtain Cu₂O layer on the substrate to prepare Cu/rGO/n-Cu₂O. Boiling time controls the amount of Cu₂O formed on it. During the boiling a fixed volume of CuSO₄ solution was maintained to provide the same experimental conditions for different preparations. The pH readings of the CuSO₄ solution after boiling were obtained using Adwa AD1030 pH/mV and Temperature Meter. Schematic structures were presented in Fig.1.b for both Cu/n-Cu₂O and Cu/rGO/n-Cu₂O photo-electrodes.

Fig. 1.b: Schematic Diagrams for Electrons Flowing of Cu/ n-Cu₂O Electrode Before and After Introducing rGO

2.4. Characterization Techniques

Diffuse reflectance spectra of Cu/n-Cu₂O and Cu/rGO/n-Cu₂O were obtained by using SHIMADZU 1800 UV spectrophotometer. The photocurrent measurements were done using Hokuto Denko HA-131 potentiostat. Here a Pt plate was used as the counter electrode, an Ag/AgCl electrode was used as the reference electrode and fabricated samples were used as the working electrode. (10⁻²M)Fe²⁺/Fe³⁺(10⁻⁴M) solution was used as the electrolyte.

3. Results and Discussion

3.1. The Variation of the Photocurrent with Boiling Time in CuSO₄ (10⁻⁴M) Solution

Fig. 2.a shows the variation of the photocurrent with boiling period of copper sheets in 10⁻⁴M CuSO₄ solution. It is clearly seen that photocurrent is maximized at 45 min boiling period producing n-Cu₂O on copper sheets reporting $\approx 1\text{mA}/\text{cm}^2$. Fig. 2.b shows the variation of the photocurrent with boiling period in 10⁻⁴M CuSO₄ solution of Cu/rGO electrodes. In this case at around 30 min boiling period higher value of steady photocurrent $\approx 1.5\text{mA}/\text{cm}^2$ is reported with compared to that of bare n-Cu₂O as shown in Fig. 2.b.

Fig. 2.a: The Variation of Photocurrent with Various Boiling Periods of Copper Sheets in 10^{-4}M CuSO_4 Solution

Fig. 2.b: The Variation of Photocurrent with Different Boiling Periods of Cu/rGO Electrodes in 10^{-4}M CuSO_4 Solution

Fig. 3 shows the variation of $\text{n-Cu}_2\text{O}$ amount produced with time, on bare copper sheets and Cu/rGO respectively. In case of Cu/rGO/ $\text{n-Cu}_2\text{O}$, saturation was reached before the saturation of $\text{n-Cu}_2\text{O}$ amount produced on copper sheets. So that it can be concluded that the formation of $\text{n-Cu}_2\text{O}$ is much efficient on Cu/rGO electrode with compared to the $\text{n-Cu}_2\text{O}$ fabrication on bare copper sheets according to the chemical reaction presented as follows. ie

3.2. pH Variation of the 10^{-4}M CuSO_4 Boiling Solution

The pH variation of CuSO_4 solution, when Cu_2O layer grows on the Cu plate and Cu/rGO electrodes as a function of boiling time, is shown in Fig. 4. It shows rapid reduction

at the beginning and saturates at around 4 for both cases. However it should be mentioned that the saturation of pH immediately occurs for Cu/rGO electrodes with compared to that of n-Cu₂O produced bare copper system. This observation also confirms that the formation of n-Cu₂O is much efficient when it is fabricated on Cu/rGO. It is well known that rGO can acts as a good electron acceptor [9]. So that rGO facilitates repelling Cu²⁺ ions from the solution to reach Cu on the copper substrate very fast to form quality n-Cu₂O layer on Cu/rGO decreasing the pH very rapidly.

Fig. 6: Photo Current Action Spectra of (a) Cu/ n-Cu₂O (b) Cu/ rGO/ n-Cu₂O

3.3. Diffuse Reflectance Spectra and Photocurrent Action Spectra

Fig. 5 and 6 shows the diffuse reflectance spectra and photocurrent action spectra of Cu/n-Cu₂O and Cu/rGO/n-Cu₂O photo-electrodes reporting the absorption edges $\approx 648\text{nm}$ and $\approx 640\text{nm}$ respectively. Both materials exhibit $\approx 2.0\text{eV}$ as the band gap. Both shapes of the spectra are almost similar confirming that the photocurrent generation occurs only due to the light absorption of the Cu₂O films. In the photocurrent action spectra photocurrent peaks can

be observed around the corresponding absorption edges confirming the photocurrent generation operates due to band to band transitions of both semiconductor films. The photocurrent enhancement is clearly observed for the Cu/rGO/n-Cu₂O photo-electrodes. Since the rGO facilitates to reach the Cu²⁺ ions towards the copper surface uniform film formation and good crystalline properties can be expected for the n-Cu₂O films prepared on rGO with improved absorption properties. Another advantage of the rGO film under the n-Cu₂O is the facilitation to collect photo-generated electrons readily suppressing the electron hole pair recombination.

4. Conclusions

Cu/rGO/n-Cu₂O photoelectrodes exhibit enhanced photocurrent at electrolyte interface. Good crystalline properties and efficient electron-hole separation can be expected for n-Cu₂O deposited rGO films. rGO supports to improve the absorption properties of the n-Cu₂O films deposited on Cu/rGO.
